Introduction to Software Technology

4. GRASP Patterns

Klaus Ostermann
GRASP Patterns

Object Design:

“After identifying your requirements and creating a domain model, then add methods to the software classes, and define the messaging between the objects to fulfill the requirements.”

But how?

- What method belongs where?
- How should the objects interact?
- This is a critical, important, and non-trivial task
GRASP Patterns

- The GRASP patterns are a learning aid to
  - help one understand essential object design
  - apply design reasoning in a methodical, rational, explainable way.

- This approach to understanding and using design principles is based on patterns of assigning responsibilities
GRASP - Responsibilities

- Responsibilities are related to the obligations of an object in terms of its behavior.

- Two types of responsibilities:
  - knowing
  - doing

- Doing responsibilities of an object include:
  - doing something itself, such as creating an object or doing a calculation
  - initiating action in other objects
  - controlling and coordinating activities in other objects

- Knowing responsibilities of an object include:
  - knowing about private encapsulated data
  - knowing about related objects
  - knowing about things it can derive or calculate
Design patterns in architecture

- **A pattern** is a recurring solution to a standard problem, in a context.

- Christopher Alexander, professor of architecture...
  - *Why is what a prof of architecture says relevant to software?*
  - “A pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice.”
Patterns in engineering

- *How do other engineers find and use patterns?*
  - Mature engineering disciplines have handbooks describing successful solutions to known problems
  - Automobile designers don't design cars from scratch using the laws of physics
  - Instead, they *reuse* standard designs with successful track records, learning from experience
  - *Should software engineers make use of patterns? Why?*
  - Developing software from scratch is also expensive
    - Patterns are a form of *reuse* of software design
Definitions and names

- Alexander: “A pattern is a recurring solution to a standard problem, in a context.”
- Larman: “In OO design, a pattern is a named description of a problem and solution that can be applied in new contexts; ideally, a pattern advises us on how to apply the solution in varying circumstances and considers the forces and trade-offs.”
Basic Pattern Principles

- Patterns are never invented; they are *found*
  - they codify existing tried-and-true knowledge, idioms, and principles
  - the more honed and widely used, the better
- Patterns give a name to an idea!

*Fred*: "Where do you think we should place the responsibility for creating a SalesLineItem? I think a Factory."

*Wilma*: "By Creator, I think Sale will be suitable."

*Fred*: "Oh, right - I agree."
GRASP

- Name chosen to suggest the importance of grasping fundamental principles to successfully design object-oriented software
- Acronym for General Responsibility Assignment Software Patterns
  - (technically “GRASP Patterns” is hence redundant but it sounds better)
- Describe fundamental principles of object design and responsibility
- Expressed as patterns
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Information Expert

- Problem: What is a general principle of assigning responsibilities to objects?
- Solution: Assign a responsibility to the information expert
  - the class that has the information necessary to fulfill the responsibility
- Start assigning responsibilities by clearly stating responsibilities!
- For instance, in a POS application a statement might be: “Who should be responsible for knowing the grand total of a sale”?
Information Expert

- What information is needed to determine the grand total?

- *Sale* is the information expert for this responsibility.
What information is needed to determine the line item subtotal?
Information Expert

- To fulfill the responsibility of knowing and answering its subtotal, a SalesLineItem needs to know the product price.
- The ProductSpecification is an information expert on answering its price; therefore, a message must be sent to it asking for its price.
To fulfill the responsibility of knowing and answering the sale's total, three responsibilities were assigned to three design classes of objects:

<table>
<thead>
<tr>
<th>Design Class</th>
<th>Responsibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sale</td>
<td>knows sale total</td>
</tr>
<tr>
<td>SalesLineItem</td>
<td>knows line item subtotal</td>
</tr>
<tr>
<td>ProductSpecification</td>
<td>knows product price</td>
</tr>
</tbody>
</table>
Information Expert: Final Design
Information Expert: Discussion

- Expert usually leads to designs where a software object does those operations that are normally done to the inanimate real-world thing it represents
  - a sale does not tell you its total; it is an inanimate thing
- In OO design, all software objects are "alive" or "animated," and they can take on responsibilities and do things.
- They do things related to the information they know.
Information Expert: Discussion

- **Contraindication: Conflict with separation of concerns**
  - Example: Who is responsible for saving a sale in the database?
  - Adding this responsibility to Sale would distribute database logic over many classes → low cohesion

- **Contraindication: Conflict with late binding**
  - Late binding is available only for the receiver object
  - But maybe the variability of late binding is needed in some method argument instead
  - Example: Support for multiple serialization strategies
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Problem:
Assign responsibility for creating a new instance of some class?

Solution:
Determine which class should create instances of a class based on the relationship between potential creator classes and the class to be instantiated.
who has responsibility to create an object?

By creator, assign class B responsibility of creating instance of class A if

- B *aggregates* A objects
- B *contains* A objects
- B *records* instances of A objects
- B *closely* uses A objects
- B *has the initializing data* for creating A objects

where there is a choice, prefer

- B *aggregates* or *contains* A objects
Who is responsible for creating *SalesLineItem* objects?
Look for a class that aggregates or contains *SalesLineItem* objects.
Creator : Example

Creator pattern suggests Sale.

Collaboration diagram is
Creator

- Promotes low coupling by making instances of a class responsible for creating objects they need to reference
- By creating the objects themselves, they avoid being dependent on another class to create the object for them
Contraindications:

- creation may require significant complexity, such as
  - using recycled instances for performance reasons
  - conditionally creating an instance from one of a family of similar classes based upon some external property value
  - Sometimes desired to outsource object wiring (“dependency injection”)

Related patterns:

- Abstract Factory, Singleton, Dependency Injection
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Low Coupling

Problem:
- How to support low dependency, low change impact, and increased reuse.

Solution:
- Assign a responsibility so that coupling remains low.
Why High Coupling is undesirable

- Coupling is a measure of how strongly one element is connected to, has knowledge of, or relies on other elements.

- An element with low (or weak) coupling is not dependent on too many other elements (classes, subsystems, ...)
  - "too many" is context-dependent

- A class with high (or strong) coupling relies on many other classes.
  - Changes in related classes force local changes.
  - Such classes are harder to understand in isolation.
  - They are harder to reuse because its use requires the additional presence of the classes on which it is dependent.
Low Coupling

How can we make classes independent of other classes?

changes are localised
easier to understand
easier to reuse

Who has responsibility to create a payment and associate it to a sale?
Low Coupling

Two possibilities:

1. Register

2. Sale

Low coupling suggests Sale because Sale has to be coupled to Payment anyway (Sale knows its total).
Common Forms of Coupling in OO Languages

- TypeX has an attribute (data member or instance variable) that refers to a TypeY instance, or TypeY itself.
- TypeX has a method which references an instance of TypeY, or TypeY itself, by any means.
  - Typically include a parameter or local variable of type TypeY, or the object returned from a message being an instance of TypeY.
- TypeX is a direct or indirect subclass of TypeY.
- TypeY is an interface, and TypeX implements that interface.
Low Coupling: Discussion

- Low Coupling is a principle to keep in mind during all design decisions.
- It is an underlying goal to continually consider.
- It is an *evaluative principle* that a designer applies while evaluating all design decisions.
- Low Coupling supports the design of classes that are more independent.
  - reduces the impact of change.
- Can't be considered in isolation from other patterns such as Expert and High Cohesion.
- Needs to be included as one of several design principles that influence a choice in assigning a responsibility.
Low Coupling: Discussion

- Subclassing produces a particularly problematic form of high coupling
  - Dependence on implementation details of superclass
  - “Fragile Base Class Problem” [see SE Design Lecture]

- Extremely low coupling may lead to a poor design
  - Few incohesive, bloated classes do all the work; all other classes are just data containers

- Contraindications: High coupling to very stable elements is usually not problematic
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
High Cohesion

Problem:
   How to keep complexity manageable.

Solution:
   Assign responsibilities so that cohesion remains high.

Cohesion is a measure of how strongly related and focused the responsibilities of an element are.

An element with highly related responsibilities, and which does not do a tremendous amount of work, has high cohesion.
High cohesion

- Classes are easier to maintain
- Easier to understand
- Often support low coupling
- Supports reuse because of fine grained responsibility
High Cohesion

Who has responsibility to create a *payment*?

1. Register

looks OK if *makePayment* considered in isolation, but adding more system operations, *Register* would take on more and more responsibilities and become less cohesive.
High Cohesion

Giving responsibility to *Sale* supports higher cohesion in *Register*, as well as low coupling.
High Cohesion: Discussion

- **Scenarios:**
  - Very Low Cohesion: A Class is solely responsible for many things in very different functional areas.
  - Low Cohesion: A class has sole responsibility for a complex task in one functional area.
  - High Cohesion. A class has moderate responsibilities in one functional area and collaborates with classes to fulfil tasks.

- **Advantages:**
  - Classes are easier to maintain
  - Easier to understand
  - Often support low coupling
  - Supports reuse because of fine grained responsibility

- **Rule of thumb:** a class with high cohesion has a relatively small number of methods, with highly related functionality, and does not do too much work.
Problem: High Cohesion and Viewpoints

[Harrison & Ossher '93]
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Controller

Problem:
Who should be responsible for handling an input system event?

Solution:
Assign the responsibility for receiving or handling a system event message to a class representing the overall system, device, or subsystem (facade controller) or a use case scenario within which the system event occurs (use case controller)
Controller: Example

Which class of object should be responsible for receiving this system event message?

It is sometimes called the controller or coordinator. It does not normally do the work, but delegates it to other objects.

The controller is a kind of "facade" onto the domain layer from the interface layer.
Controller: Example

- By the Controller pattern, here are some choices:
- *Register, POSSystem*: represents the overall "system," device, or subsystem
- *ProcessSaleSession, ProcessSaleHandler*: represents a receiver or handler of all system events of a use case scenario
Controller: Discussion

- Normally, a controller should delegate to other objects the work that needs to be done; it coordinates or controls the activity. It does not do much work itself.
- Facade controllers are suitable when there are not "too many" system events.
- A use case controller is an alternative to consider when placing the responsibilities in a facade controller leads to designs with low cohesion or high coupling.
  - typically when the facade controller is becoming "bloated" with excessive responsibilities.
Controller: Discussion

- **Benefits**
  - Increased potential for reuse, and pluggable interfaces
    - No application logic in the GUI
  - Dedicated place to place state that belongs to some use case
    - E.g. operations must be performed in a specific order
- **Avoid bloated controllers!**
  - E.g. single controller for the whole system, low cohesion, lots of state in controller
  - Split into use case controllers, if applicable
- Interface layer does not handle system events
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Polymorphism

Problem:

How to handle alternatives based on types?
How to create pluggable software components?

Solution:

When alternate behaviours are selected based on the type of an object, use polymorphic method call to select the behaviour, rather than using if/case statement to test the type.
Polymorphism: Example
Polymorphism: Discussion

- Polymorphism is a fundamental principle in designing how a system is organized to handle similar variations.

- Properties:
  - Easier and more reliable than using explicit selection logic
  - Easier to add additional behaviors later on
  - Increases the number classes in a design
  - May make the code less easy to follow

- Using the principle excessively for “future-proofing” against yet unknown potential future variations is a bad idea
  - Agile methods recommend to do no significant “upfront design” and add the variation point only when the need arises
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Pure Fabrication

Problem:
Adding some responsibilities to domain objects would violate high cohesion/low coupling/reuse

Solution:
Assign a highly cohesive set of responsibilities to an artificial or convenience class that does not represent a problem domain concept—something made up, to support high cohesion, low coupling, and reuse.
Pure Fabrication: Example

- In the point of sale example support is needed to save Sale instances in a relational database.
- By Expert, there is some justification to assign this responsibility to Sale class.
- However, the task requires a relatively large number of supporting database-oriented operations and the Sale class becomes incohesive.
- The sale class has to be coupled to the relational database increasing its coupling.
- Saving objects in a relational database is a very general task for which many classes need support. Placing these responsibilities in the Sale class suggests there is going to be poor reuse or lots of duplication in other classes that do the same thing.
Pure Fabrication: Example

- Solution: create a new class that is solely responsible for saving objects in a persistent storage medium
- This class is a Pure Fabrication

- The Sale remains well-designed, with high cohesion and low coupling
- The PersistentStorageBroker class is itself relatively cohesive
- The PersistentStorageBroker class is a very generic and reusable object
The design of objects can be broadly divided into two groups:
- Those chosen by representational decomposition (e.g. Sale)
- Those chosen by behavioral decomposition (e.g. an algorithm object such as TOCGenerator or PersistentStorage)

Both choices are valid designs, although the second one corresponds less well to the modeling perspective on objects.

If overused, it can lead to a non-idiomatic design, namely a separation of the code into data and behavior as in procedural programming.

Coupling of data and behavior is central to OO design.
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Indirection

Problem:
Where to assign a responsibility, to avoid direct coupling between two (or more) things?
How to de-couple objects so that low coupling is supported and reuse potential remains higher?

Solution:
Assign the responsibility to an intermediate object to mediate between other components or services, so that they are not directly coupled.

"Most problems in computer science can be solved by another level of indirection"
By adding a level of indirection and adding polymorphism, the adapter objects protect the inner design against variations in the external interfaces.
Nine GRASP patterns:

- Information Expert
- Creator
- Low Coupling
- Controller
- High Cohesion
- Polymorphism
- Indirection
- Pure Fabrication
- Protected Variations
Protected Variation

Problem:
How to design objects, subsystems, and systems so that the variations or instability in these elements does not have an undesirable impact on other elements?

Solution:
Identify points of predicted variation or instability; assign responsibilities to create a stable interface around them.

*Note: This is basically just another formulation of the information hiding principle.*
Protected Variation: Examples

- Data encapsulation, interfaces, polymorphism, indirection, and standards are motivated by PV.
- Virtual machines are complex examples of indirection to achieve PV
- Service lookup: Clients are protected from variations in the location of services, using the stable interface of the lookup service.
- Uniform Access Principle
- Law of Demeter
- ...
